

## FEATURES

- Single Supply Operation (+8V to +22V)
- Pulse Output Compatible with All Logic Forms
- Programmable Scale Factor (K)
- Linearity  $\pm 0.05\%$  Typical-precision Mode
- Temperature Stability  $\pm 100\text{ ppm}/^\circ\text{C}$  Typical
- High Noise Rejection
- Inherent Monotonicity
- Easily Transmittable Output
- Simple Full Scale Trim
- Single-Ended Input, Referenced to Ground
- Also Provides Frequency-to-Voltage Conversion
- Direct Replacement for RC/RV/RM-4151

## APPLICATIONS

- Voltage-to-Frequency Conversion
- A/D and D/A Conversion
- Data Transmission
- Frequency-to-Voltage Conversion
- Transducer Interface
- System Isolation

## GENERAL DESCRIPTION

The XR-4151 is a device designed to provide a simple, low-cost method for converting a DC voltage into a proportional pulse repetition frequency. It is also capable of converting an input frequency into a proportional output

voltage. The XR-4151 is useful in a wide range of applications including A/D and D/A conversion and data transmission.

## ORDERING INFORMATION

Part No.	Package	Operating Temperature Range
XR-4151P	8 Lead 300 Mil PDIP	-40°C to +85°C
XR-4151CP	8 Lead 300 Mil PDIP	0°C to +70°C
XR-4151MD	8 Lead 4.4mm EIAJ SOP	0°C to +70°C

Input Voltage ..... -0.2V to +V<sub>CC</sub>  
 Output Short Circuit to Ground ..... Continuous

## SYSTEM DESCRIPTION

The XR-4151 is a precision voltage-to-frequency converter featuring 0.05% conversion linearity (precision mode), high noise rejection, monotonicity, and single supply operation from 8V to 22V. An RC network on Pin 5 gets the maximum full wave frequency. Input voltage on Pin 7 is compared with the voltage on Pin 6 (which is generally controlled by the current source output, Pin 1). Frequency output is proportioned to the voltage on Pin 7. The current source is controlled by the resistance on Pin 2 (nominally 14k $\Omega$  with  $I = 1.9 \text{ V/R}$ ). The output is an open collector at Pin 3.

## PRINCIPLES OF OPERATION

### Single Supply Mode Voltage-to-Frequency Converter

In this application, the XR-4151 functions as a stand alone voltage-to-frequency converter operating on a single positive power supply. Refer to the functional block diagram and *Figure 2*, the circuit connection for single supply voltage-to-frequency conversion. The XR-4151 contains a voltage comparator, a one-shot, and a

precision switched current source. The voltage comparator compares a positive input voltage applied at pin 7 to the voltage at pin 6. If the input voltage is higher, the comparator will fire the one-shot. The output of the one-shot is connected to both the logic output and the precision switched current source. During the one-shot period,  $T$ , the logic output will go low and the current source will turn on with current  $I$ . At the end of the one shot period the logic output will go high and the current source will shut off. At this time the current source has injected an amount of charge  $Q = I_O T$  into the network  $R_B - C_B$ . If this charge has not increased the voltage  $V_B$  such that  $V_B > V_I$ , the comparator again fires the one-shot and the current source injects another,  $Q$ , into the  $R_B - C_B$  network. This process continues until  $V_B > V_I$ . When this condition is achieved, the current source remains off and the voltage  $V_B$  decays until  $V_B$  is again equal to  $V_I$ . This completes one cycle. The VFC will now run in a steady state mode. The current source charges the capacitor  $C_B$  at a rate such that  $V_B \geq V_I$ . Since the discharge rate of capacitor  $C_B$  is proportional to  $V_B / R_B$ , the frequency at which the system runs will be proportional to the input voltage.

Figure 2. Voltage-to-Frequency Converter

## TYPICAL APPLICATIONS

### Single Supply Voltage-to-Frequency Converter

Figure 2 shows the simplest type of VFC that can be made with the XR-4151. The input voltage range is from 0 to +10V, and the output frequency is from 0 to 10kHz. The full scale frequency can be tuned by adjusting  $R_S$ , the output current set resistor. This circuit has the advantage of being simple and low in cost, but it suffers from inaccuracy due to a number of error sources. Linearity error is typically 1%. A frequency offset will also be

introduced by the input comparator offset voltage. Also, response time for this circuit is limited by the passive integration network  $R_B C_B$ . For the component values shown in Figure 2, response time for a step change input from 0 to +10V will be 135msec. For applications which require fast response time and high accuracy, use the circuit of Figure 3.

## Precision Voltage-to-Frequency Converter

In this application (*Figure 3*) the XR-4151 is used with an operational amplifier integrator to provide typical linearity of 0.05% over the range of 0 to -10V. Offset is adjustable to zero. Unlike many VFC designs which lose linearity below 10mV, this circuit retains linearity over the full range of input voltage, all the way to 0V.

Trim the full scale adjust pot at  $V_I = -10V$  for an output frequency of 10kHz. The offset adjust pot should be set for 10Hz with an input voltage of -10mV.

The operational amplifier integrator improves linearity of this circuit over that of *Figure 2* by holding the output of the source, Pin 1, at a constant 0V. Therefore, the linearity

error due to the current source output conductance is eliminated. The diode connected around the operational amplifier prevents the voltage at pin 7 of the XR-4151 from going below 0. Use a low-leakage diode here, since any leakage will degrade the accuracy. This circuit can be operated from a single positive supply if an XR-3403 ground-sensing operational amplifier is used for the integrator. In this case, the diode can be left out. Note that even though the circuit itself will operate from a single supply, the input voltage is necessarily negative. For operations above 10kHz, bypass pin 6 of the XR-4151 with .01 $\mu$ F.

Figure 3. Precision Voltage to Frequency Converter

## Frequency-to-Voltage Conversion

The XR-4151 can be used as a frequency-to-voltage converter. *Figure 4* shows the single-supply FVC configuration. With no signal applied, the resistor bias networks tied to pins 6 and 7 hold the input comparator in the off state. A negative going pulse applied to pin 6 (or positive pulse to pin 7) will cause the comparator to fire the one-shot. For proper operation, the pulse width must be less than the period of the one-shot,  $T = 1.1 R_0 C_0$ . For a 5Vpp square-wave input the differentiator network formed by the input coupling capacitor and the resistor bias network will provide pulses which correctly trigger the one-shot. An external voltage comparator can be used to “square-up” sinusoidal input signals before they are applied to the XR-4151. Also, the component values for the input signal differentiator and bias network can be altered to accommodate square waves with different

amplitudes and frequencies. The passive integrator network  $R_B C_B$  filters the current pulses from the pin 1 output. For less output ripple, increase the value of  $C_B$ .

For increased accuracy and linearity, use an operational amplifier integrator as shown in *Figure 5*, the precision FVC configuration. Trim the offset to give -10mV out with 10Hz in and trim the full scale adjust for -10V out with 10kHz in. Input signal conditioning for this circuit is necessary just as for the single supply mode and the scale factor can be programmed by the choice of component values. A tradeoff exists between the amount of output ripple and the response time, through the choice of integration capacitor  $C_1$ . If  $C_1 = 0.1\mu\text{F}$  the ripple will be about 100mV. Response time constant  $\tau_R = R_B C_1$ . For  $R_B = 100\text{k}\Omega$  and  $C_1 = 0.1\mu\text{F}$ ,  $\tau_R = 10\text{msec}$ .

#### Figure 4. Frequency to Voltage Converter

## Precautions

1. The voltage applied to comparator input pins 6 and 7 should not be allowed to go below ground by more than 0.3V.
2. Pins 3 and 5 are open-collector outputs. Shorts between these pins and  $V_{CC}$  can cause overheating and eventual destruction.
3. Reference voltage terminal pin 2 is connected to the emitter of an NPN transistor and is held at approximately 1.9V. This terminal should be protected from accidental shorts to ground or supply voltages. Permanent damage may occur if the current in pin 2 exceeds 5mA.
4. Avoid stray coupling between pins 5 and 7; it could cause false triggering. For the circuit of Figure 2, bypass pin 7 to ground with at least  $0.01\mu\text{F}$ . This is necessary for operation above 10kHz.

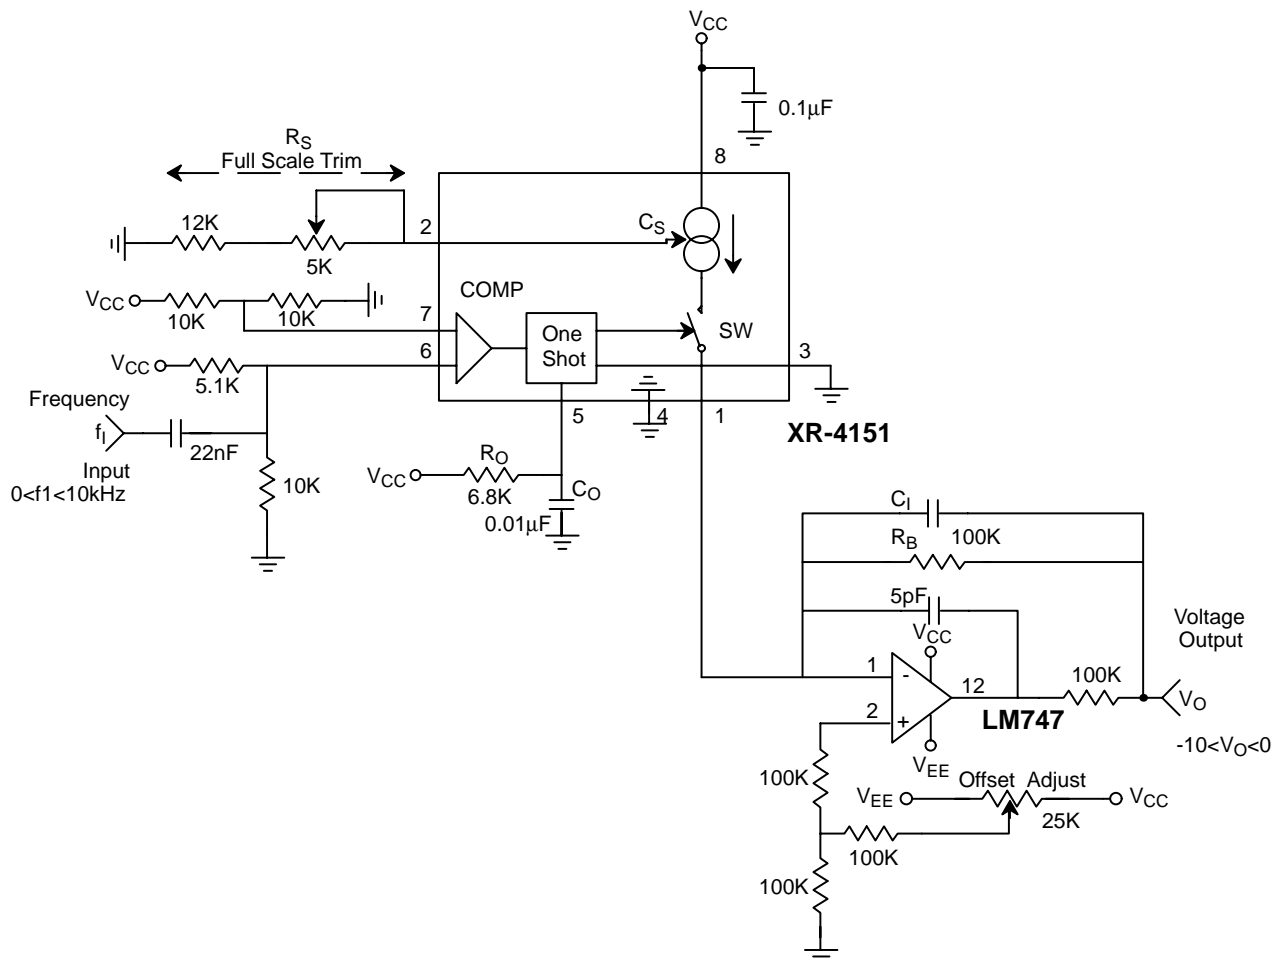

Figure 5. Precision Frequency-to-Voltage Converter

## Programming the XR-4151

The XR-4151 can be programmed to operate with a full scale frequency anywhere from 1.0Hz to 100kHz. In the case of the VFC configuration, nearly any full scale input voltage from 1.0V and up can be tolerated if proper scaling is employed. Here is how to determine component values for any desired full scale frequency.

1. Set  $R_S = 14k\Omega$  or use a 12K resistor and 5K pot as shown in the figures. (The only exception to this is *Figure 3*).
2. Set  $T = 1.1 \cdot R_0 \cdot C_0 = 0.75 [1/f_0]$  where  $f_0$  is the desired full scale frequency. For optimum performance make  $6.8k\Omega > R_0 > 680k\Omega$  and  $0.001\mu F < C_0 < 1.0\mu F$ .
3. a) For the circuit of *Figure 2* make  $C_B = 10^{-2} [1/f_0]$  Farads.  
Smaller values of  $C_B$  will give a faster response time, but will also increase the frequency offset and nonlinearity.  
b) For the active integrator circuit make  
 $C_I = 5 \times 10^{-5} [1/f_0]$  Farads.  
The operational amplifier integrator must have a slew rate of at least  $135 \times 10^{-6} [1/C_I]$  volts per second where the value of  $C_I$  is in Farads.
4. a) For the circuit of *Figure 3* keep the values of  $R_B$  as shown and use an input attenuator to give the desired full scale input voltage.  
b) For the precision mode circuit of *Figure 3*, set  $R_B = V_{IO}/100\mu A$  where  $V_{IO}$  is the full scale input voltage.  
Alternately, the operational amplifier inverting input (summing node) can be used as a current input with the full scale input current  $I_{IO} = -100\mu A$ .
5. For the FVC's, pick the value of  $C_B$  or  $C_I$  to give the optimum tradeoff between the response time and output ripple for the particular application.

## Design Example

- I. Design a precision VFC (from *Figure 4*) with  $f_0 = 100kHz$  and  $V_{IO} = -10V$ .
  1. Set  $R_S = 14.0k\Omega$ .

$$2. T = 0.75 [1/10^5] = 7.5\mu sec.$$

$$\text{Let } R_0 = 6.8k\Omega \text{ and } C_0 = 0.001\mu F.$$

$$3. C_I = 5 \times 10^{-5} [1/10^5] = 500pF.$$

Op amp slew rate must be at least

$$SR = 135 \times 10^{-6} [1/500pF] = 0.27V/\mu sec.$$

$$4. R_B = 10V/100\mu A = 100k\Omega.$$

- II. Design a precision VFC with  $f_0 = 1Hz$  and  $V_{IO} = 10V$ .

$$1. \text{ Let } R_S = 14.0k\Omega.$$

$$2. T = 0.75 [1/1] = 0.75 \text{ sec.}$$

$$\text{Let } R_0 = 680k\Omega \text{ and } C_0 = 1.0\mu F.$$

$$3. C_I = 5 \times 10^{-5} [1/1]F = 50\mu F.$$

$$4. R_B = 100k\Omega.$$

- III. Design a single supply FVC to operate with a supply voltage of 9V and full scale input frequency  $f_0 = 83.3Hz$ . The output voltage must reach at least 0.63 of its final value in 200msec. Determine the output ripple.

$$1. \text{ Set } R_S = 14.0k\Omega.$$

$$2. T = 0.75 [1/83.3] = 9msec.$$

$$\text{Let } R_0 = 82k\Omega \text{ and } C_0 = 0.1\mu F.$$

3. Since this FVC must operate from 8.0V, we shall make the full scale output voltage at pin 6 equal to 5.0V.

$$4. R_B = 5V/100\mu A = 50k\Omega.$$

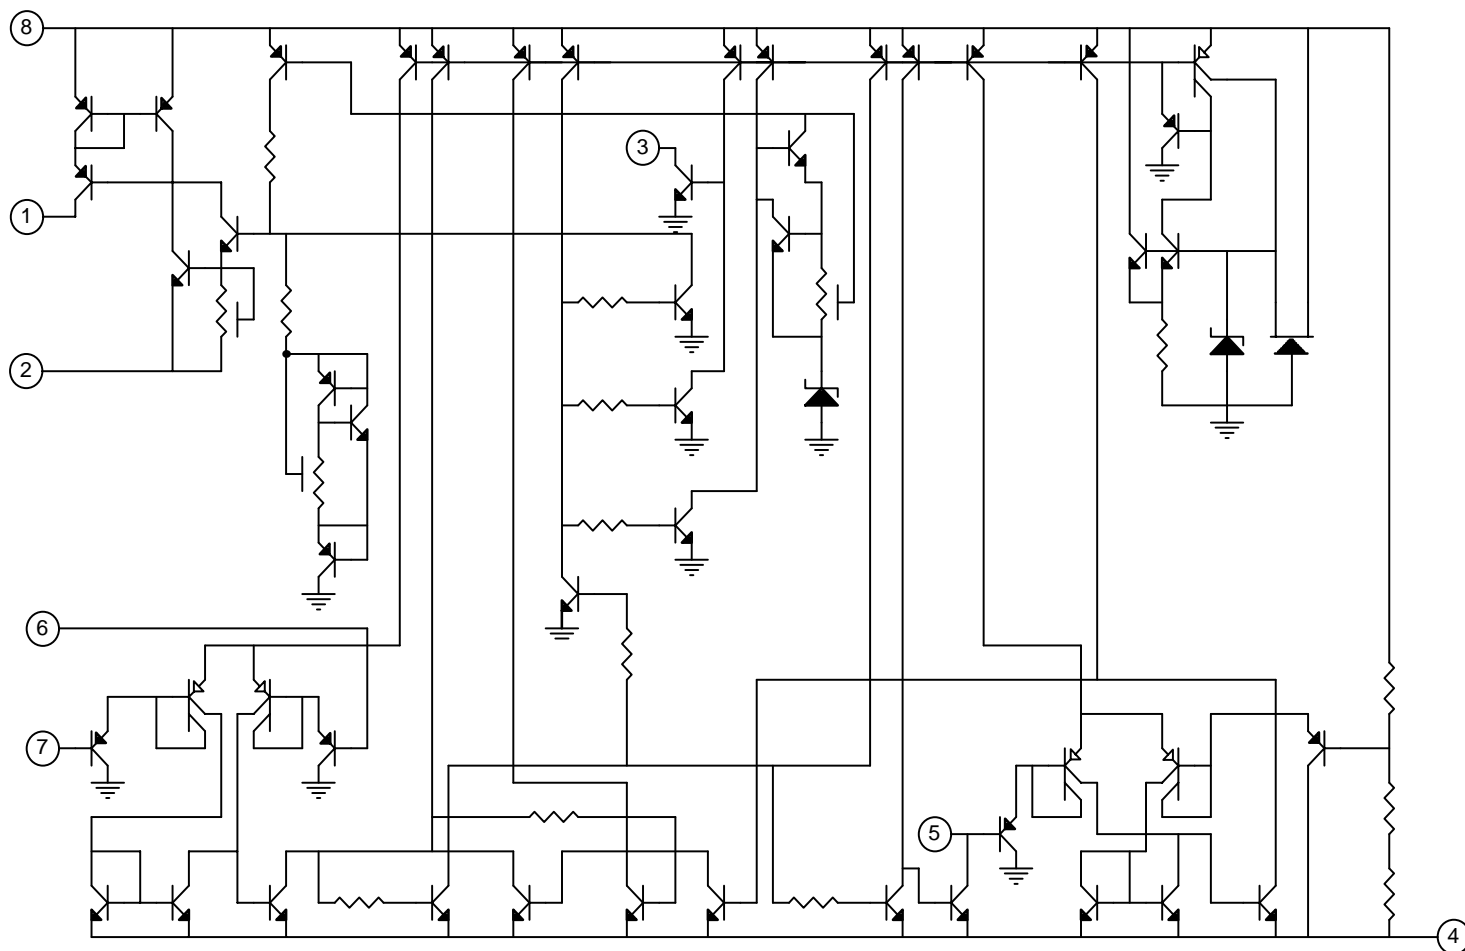

$$5. \text{ Output response time constant is } \tau_R \leq 200msec.$$

Therefore,

$$C_B \leq \tau_R/R_B = (200 \times 10^{-3})/(50 \times 10^3) = 4\mu F.$$

Worst case ripple voltage is

$$V_R = (9ms \times 135\mu A)/4\mu F = 304mV.$$
